Molar Mass Determination

Using Freezing Point Depression Measurements

Freezing Point Depression: the phenomenon of a solvent's freezing point decreasing as a solute is added to the solvent

Colligative Property: when solute effects on solvent are 'independent' of nature or type of solute.

These properties are often used to determine the molar mass of a substance.

example 1 - boiling point elevation by addition of a solute to solvent.

Adding salt to water at high elevation to increase boiling point

$T_b(\text{H}_2\text{O}) \sim 100^\circ\text{C}$ at 1 atmosphere
at high elevation, T_b ___ as P ___
if add enough salt, T_b ___ as [salt] ___

explanation: salt atoms at the surface decrease H_2O molecules probability for escape

example 2 - freezing point depression by addition of a solute to solvent.

Adding salt to ice on roads to decrease melting point

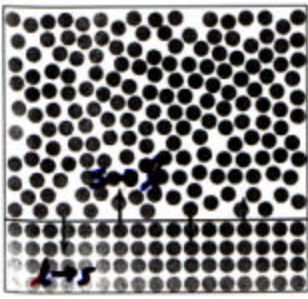

$T_f(\text{H}_2\text{O}) \sim 0^\circ\text{C}$ at 1 atmosphere
as add salt, T_f ___ as [salt] ___

explanation: solute molecules at solid/liquid interface decrease rate of solute molecule freezing, but do not affect rate of melting

Chemistry 1M/N Lab Lecture Notebook

WHY FREEZING POINT DEPRESSION?

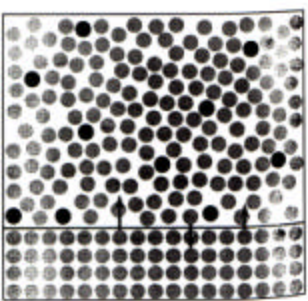

pure solvent

pure solid

T_f is temperature where
 $\text{rate}_{s \rightarrow l} = \text{rate}_{l \rightarrow s}$
 (liq.-sol. equilibrium)

solvent with solute

pure solid

addition of solute to solvent decreases $\text{rate}_{l \rightarrow s}$ only.
 Temperature must be decreased to increase $\text{rate}_{l \rightarrow s}$

Olmsted + Williams (1975) making $\text{rate}_{l \rightarrow s} = \text{rate}_{s \rightarrow l}$

Freezing Point Depression $\equiv \Delta T_f \equiv T_f(\text{solvent and solute}) - T_f(\text{pure solvent})$

$$\Delta T_f \propto [\text{solute}]$$

$$\Delta T_f = -k_f[\text{solute}] = -k_f \left(\frac{n_{\text{solute}}}{m_{\text{solvent}}[\text{kg}]} \right) = -k_f \left(\frac{m_{\text{solute}}[\text{g}]}{MM_{\text{solute}} m_{\text{solvent}}[\text{kg}]} \right) \quad \underline{\text{The Equation of the Day}}$$

Procedure

1. Clean test tube. Dry and rinse with cyclohexane.
2. Weigh empty test tube and stir bar.
3. Add ~20ml of cyclohexane and reweigh.
4. Cool in ice-water slurry. At $\sim 13^{\circ}\text{C}$, begin temperature-time measurements

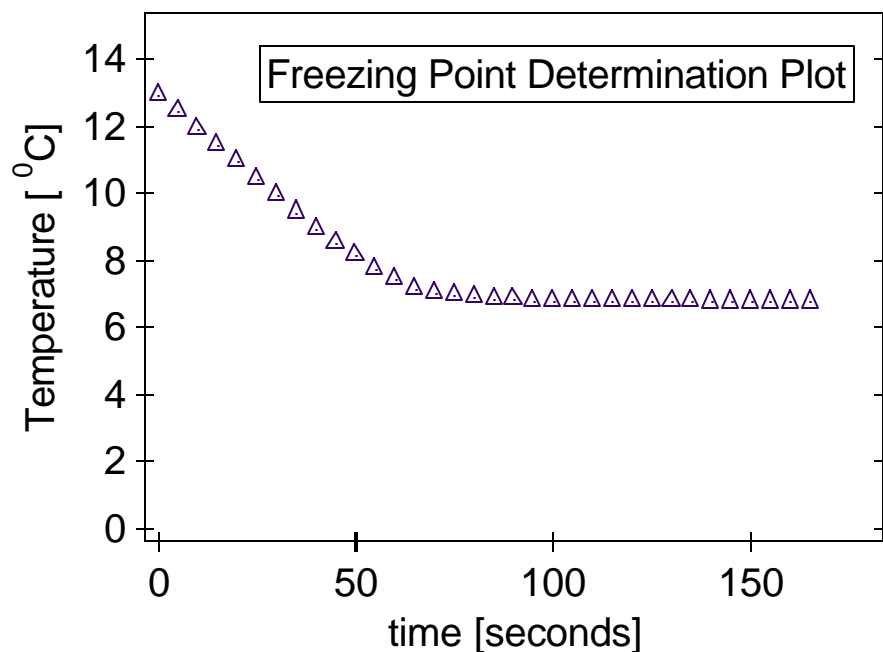

T ($^{\circ}\text{C}$)	t (seconds)

Record T every 5 seconds, until ΔT becomes small (every 10 seconds).
Take several measurements at minimal change (long time).

5. For $\Delta T_f = f(\text{molality})$, add solute to cyclohexane
(weigh the solute on the analytical balance)
Repeat step 4.

Data Analysis

From time-Temperature data, prepare Freezing Point Determination graphs.

$T_f = \underline{\hspace{2cm}}$

Results Table prepared from analysis of Freezing Point Determination graphs.

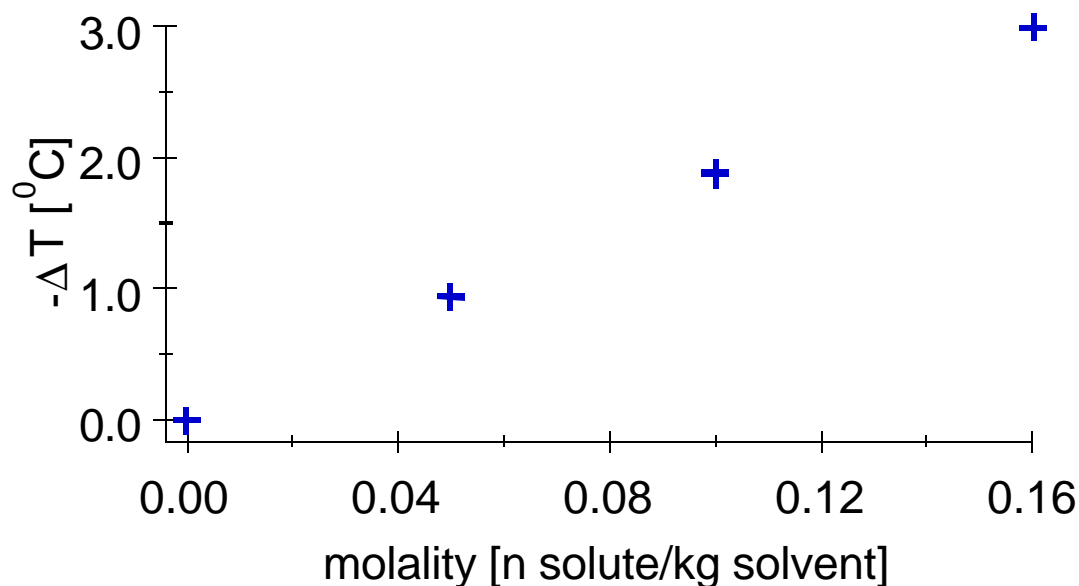

T_f (°C)	ΔT_f (°C)	[solute] (molality)

Use results in the following K_f determination graph.

Chemistry 1M/N Lab Lecture Notebook

K_f determination for cyclohexane.

Using $\Delta T_f = -K_f [\text{solute}]$,
graph ___ versus ___
and determine slope, K_f .

slope = K_f because $-\Delta T_f = K_f [\text{solute}]$.

Determination of unknown molar mass.

$$\text{rearranging } \Delta T_f = -K_f \left(\frac{m_{\text{solute (g)}}}{MM_{\text{solute}} m_{\text{solvent (kg)}}} \right)$$

$$\text{gives } MM_{\text{solute}} = \frac{-K_f \cdot m_{\text{solute (g)}}}{\Delta T_f \cdot m_{\text{solvent (kg)}}}$$
